Key words
Financial Reporting, Earnings Management, Firm Characteristics

Abstract
Earnings management has been a great and consistent concern among practitioners and regulators and has received considerable attention in the accounting literature. Several techniques and reasons exist for the practice of earnings management each is based on the management’s objectives. This paper aims to assess the impact of firm characteristics on earnings management of the listed firms in Egypt. It selects the 50 most active firms in the Egyptian stock exchange and the analysis is done using the financial statements from the disclosure book for the period 2007-2011. After excluding banks and insurance companies, for having different disclosure requirements and different corporate governance code, the final count for the firms included in the paper is 60 firms in five years so this leave us with a total of 300 observations. The tests for this research are done using the random effect generalized least square regression model using the Stata program. Findings found that there is a significant positive relationship between firms’ financial leverage and earnings management while other variables of the firm characteristics which are firm size, firm age and firms’ audit quality have an insignificant relationship with earnings management.

1. Introduction
A series of corporate accounting scandals were witnessed at the beginning of the 21st century across Europe and the United States and this includes several examples like Enron, WorldCom and Xerox. It is found that the core of these scandals was usually the phenomenon of earnings management (Goncharov 2005). Managers always aim to secure all the funds needed to keep the business running so that no external party can interfere, and at the same time managers aim to gain whatever kind of benefit they can from the business (Kim and Yoon 2009). Since the accounting earnings are of great importance to the stakeholders given the fact that it is the end product of the accounting process and based on the many problems and acts by the managers to try practicing earnings management, stakeholders doubt the credibility and reliability of the financial reports (Uwuigbe et al 2015).

High quality financial reporting is greatly valued by investors and other stakeholders for several reasons. One of them is that it reduces the information asymmetry problem as (Jensen and Meckling 1976) state in their research. In addition to that it provides users with more reliable information to take decisions and better reflection for the company (Wawero and Riro 2013). Moreover, as (Watts and Zimmerman 1978) add, high quality financial reporting boosts the level of transparency and helps in executing better contracts. Finally, the International Chamber of Commerce (ICC 2005) clarifies that the market efficiency and the confidence of the investors are enhanced when the reported information is reliable and of high quality in the sense of consistency, comparability and understandability.

Financial reporting mechanism focuses on promoting public confidence in the financial reporting system as well as maintaining an adequate internal control system by having a competent and independent internal audit staff, adding to this; severe sanctions should be
properly imposed if any financial statement fraud is detected (Michael 1986). Egyptian firms adhering to the letter of law by following the Egyptian Accounting Standards (EAS), in the financial reporting process, that are based on the IFRS with few exceptions (Hassan 2008), is not an indicator to the existence of the spirit of the law as earnings management practice in Egypt is well accepted (Kamel and Elbanna 2010), along with several cases of accounting and auditing malpractices which have been recently detected by the Egyptian Capital Market Authority. Moreover, the recommendations adopted by the Egyptian Corporate Governance Code are not legally binding with an absence of law enforcement so this might encourage strong managers to manipulate earnings (Khalil 2010).

The next section of the paper shows the literature and develops the research hypotheses; section 3 presents the methodology, section 4 is the findings and the conclusion, finally section 5 provides the limitations and few recommendations.

2. Literature Review

In spite of all the mechanisms adopted in the last decade in Egypt, which aim to increase the level of transparency and confidence in the content of financial reporting, the ability of companies to manipulate financial reports through the earnings management practice still exists, especially since these management practices are legal and within the flexibility allowed by the accounting standards which differ from illegal practices and that are classified as cases of fraud (Metawee 2013). It is added in a research by (Abdulrahman and Ali 2006) that earnings management practice adheres with GAAP (Generally Accepted Accounting Principles) so the practice falls within the bounds of accepted manipulations of accounting procedures and this differentiates earnings management from fraud as no violation for the rules took place, however this practice leads to inaccurate information about the company.

Earnings management is defined by (Blom 2009) as a purposeful intervention by the management in the process of financial reporting in order to gain personal benefit or for the organization. Based on this definition, earnings management is not informative for shareholders, and therefore it is opportunistic. Earnings management practice is explained by several theories, according to the signaling theory earnings are considered the indicator to the capital market to test whether the firm engaged in value adding activities during a certain period or not (Waweru and Riro 2013). While the stakeholder’s theory explains that managers might manipulate earnings in order to enhance their private interests and benefits on the expense of shareholders and additionally the rest of stakeholders (Prior et al 2008). A third theory is the famous agency theory that explains the agency problem which is due to the agent (management) acting in their own benefit and in an opportunistic manner on the expense of the principal (owners/shareholders), as proposed by (Jensen and Meckling 1976).

The rise of earnings management comes from the application of the accrual base rather than cash flow that makes it easy for the management to manipulate the financial information as accruals are less observable (Chen et al 2014). Accrual-based accounting leads to the division of total accruals into non discretionary and discretionary components. The discretionary accruals are the proportion of accruals that management chooses to report (Gul et al 2003). This indicates that by using accrual accounting managers can control the timing of revenue and expense recognition and thus can manipulate the firm’s earnings for a given period (Shah et al 2009).

Many prior literature study the determinants of earnings management however very limited research is done to investigate the impact of firm characteristics on earnings management and especially in the developing nations, so this study attempts to study the relation between firm characteristics and earnings management in a developing country, Egypt,
focusing on four main types of firm characteristics which are the ones commonly used and those are firm size, firm financial leverage, firm age, and firm's audit quality.

2.1 Firm size and earnings management

The size of a firm varies in many ways and it is essential to consider how the size affects the quality of reported information. It is argued by (Meek et al 2007) that based on the information asymmetry theory, large firms have lower information asymmetry as they have strong governance and control so this leads to the reduction of the earnings management practice. However, being a large firm is not enough reason to have a strong corporate governance level and therefore reduce earnings management practice as for instance, the fall of Enron, through practicing financial engineering, was mainly due to the failure of corporate governance, and specifically a board problem due to blindly trusting the auditors, and allowing conflict of interest to take place (Munzing 2003). Moreover, (Jensen and Meckling 1976) add that based on the agency theory, large sized firms witness greater agency costs and this means more opportunistic practices.

Several reasons exist to prove a negative relation between firm size and earnings management as explained by (Ahmad et al 2014 and Kim et al 2003), Large-sized firms may have stronger internal control system and may have more competent internal auditors as compared to small-sized firms therefore; an effective internal control system helps in publishing reliable financial information to the public, so this will likely reduce the ability of the management to manipulate earnings. Also large firms are usually audited by one of the big four auditing firms and this helps prevent earnings management due to the efficient and effective audit performed. A third reason is the reputation cost, in large firms the reputation cost is higher than that in the small firms as large firms have better appreciation of market environment, better control over their operations and better understanding of their businesses relative to small-sized firms, therefore this might prevent large firms from engaging in earnings management practices.

On the other side, a positive relation exists as large-sized firms face more pressures to meet the analysts' expectations (Barton and Simko 2002). In addition, large-sized firms have greater bargaining power with auditors so the larger the firm size, the more bargaining power they have in negotiations with auditors.

This is consistent with what some articles in the newspapers mention, as one of the articles (The Netherlands times) argues about imposing fines on the big 4 audit firms due to failure in auditing the financial statements, while the other article (The Telegraph) states that the big audit firms put the management interest before the shareholders interest, creating an agency problem. However, studies conducted produced results that confirm the importance of the existence of the big audit firms to reduce earnings management practice (Becker et al 1998 and Francis and Krishnan 1999). Although real life examples might contradict with the studies, one might prefer to depend on the studies as they are supported with analysis and results.

2.2 Firm financial leverage and earnings management

Managers who try to reduce debt covenant costs may adopt certain accounting methods that enable them to report favorable financial statements in terms of creditworthiness (Bowen and Shores 1995). Therefore there is a link between the debt level and the choice of accounting policy as (Waweru and Riro 2013) explain, debt covenants are based on the accounting numbers reported and any violation in those debt covenants imposes costs on the company and this might lead to the practice of earnings management to avoid costs, as well as improving the firm’s financial flexibility in order to prevent reflecting an image of financial distress (Easton et al 1993).
One of the theories linking the two variables is the financial distress theory explained by (Fung and Goodwin 2013) which examines earnings management incentives among managers in financial distress firms. They argue that when managers manipulate the firm’s earnings, they are doing that to convince their creditors that the financial distress is a temporary nature and will be able to recover soon. Another theory would be the information asymmetry, According to (Jones et al 2005); information asymmetries tend to be less severe for large loans, since any fixed costs associated with obtaining information about a borrower are less of an obstacle for large loans. It is also suggested that small borrowers have greater information asymmetries, and a loan’s size is typically positively correlated with its borrower’s size.

When a company relies on debt, the managers tend to choose accounting policies that increase the income so that they abide by the debt covenants imposed by banks and bondholders and this allows them to avoid any renegotiation costs (Beatty and Weber 2003). Based on the previous studies a negative relation is proposed to exist between firm's financial leverage and earnings management mainly for two reasons, first, leverage requires debt repayment, thus reduces cash available to management for non-optimal spending. Second, when a firm employs debt financing, it undergoes the scrutiny of lenders and is often subject to lender-induced spending restriction (Jensen 1986).

2.3 Firm age and earnings management

As time passes, firms discover what they are good at and learn how to do things better as they specialize more and new techniques are found to standardize, coordinate, and speed up their production processes, as well as to minimize costs and improve quality (Arrow 1962, Ericson and Pakes 1995).

Based on prior research, firms that have been in the market for long times tend to have low level of earnings management than beginners as they are well known companies, that have a great value in the market and they have a reputation to protect, also they are aware of the rules and codes that govern their practices. Moreover, long established firms might have improved their financial reporting practices over time (Alsaeed 2006) and secondly they try to enhance their reputation and image in the market (Akhtaruddin 2005) so the older the firm, the less tendency to perform earnings management practices.

When a firm is familiar in the market, debates exist on whether this will lead to the unwillingness of external parties to question the firm or not. Usually, long established firms are audited by one of the big auditing firms and based on (DeAnglo 1981) big audit firms have incentive to report material misstatements in order to protect their reputation. In addition, governmental agencies always pay attention to firms that have been in the market for a long time more than the newly entered firms, therefore, when the age increases, the firm tends to improve its governance by issuing high quality financial reports without manipulations. (Chalaki et al 2012).

On the other hand, when it comes to real life examples, Enron's scandal opposes the mentioned opinion as Enron was a well known firm that wanted to meet aggressive expectations, left a room for an agency problem and trusted the auditors and did not insure their independence (Munzing 2003). Arthur Andersen as an auditing firm was driven by greed and its main aim was to keep the client happy (Toffler 2004) therefore the audit firm did not tend to question any malpractices performed by the client and covered up Enron's manipulations and therefore performed a poor quality audit.
2.4 Firm’s audit quality and earnings management

High quality audit is more likely to detect and report errors and irregularities. Thus, it is an effective barrier to earnings manipulations (DeAngelo 1981). Auditing reduces asymmetries between managers and shareholders by allowing outsiders to verify the validity of financial statements and by that it is a valuable monitoring method used by firms to reduce agency costs (Watts and Zimmerman 1983). The big four auditing firms have a very huge incentive to maintain a high audit quality due to the following reasons, the first one is that they have large number of clients, in addition, better resources employed like the technology, training programs and experience, finally the last reason is having a reputation that might be lost if they didn’t report a misstatement or a manipulation (Rusmin 2010, and Chung et al 2005).

Firms audited with auditors other than the big four report significantly greater discretionary accruals as stated by (Lenard and Yu 2012) confirming this inverse relation (Bartov et al 2000) suggest that higher quality auditors tend to report any error and have no willingness to accept any manipulations. The study by (Yasar 2013) finds that the audit quality doesn’t have an impact on discretionary accruals so there is no difference in audit quality between Big Four and non-Big four audit firms in constraining the practice of earnings management, (Piot and Janin 2007) agreed to this finding.

Based on previous studies and results, it can be seen that large sized firms, firm financial leverage level, firm’s age and audit quality and being audited by one of the big 4 audit firms can have significant effect on management opportunistic behavior such as earnings management. Consequently, this paper proposes the following hypotheses:

H1: There is a significant relationship between Firm size and earnings management
H2: There is a significant relationship between Firm Financial Leverage and earnings management
H3: There is a significant relationship between Firm Age and earnings management
H4: There is a significant relationship between firms’ audit quality and earnings management

3. Methodology

Sample selection and data collection

The unit of analysis in this research is constituted of a population of firms that are listed in the Egyptian stock exchange (EGX) as the data will be easily accessible. Specifically, a sample of the 50 most active firms listed in the (EGX) is used from the year 2007-2011 excluding the financial institutions due to their specific and different corporate governance and disclosure requirements. Secondary data type is used as the data gathered to measure the dependent and independent variables is from the financial statements. Data source is mainly the disclosure book and some data is purchased from the Egyptian Company for Information Dissemination (EGID). This study is considering a panel data type and this will require conducting the random effect generalized least square (GLS) regression using the Stata program.

Panel Data

This section proposes the use of panel data instead of the cross sectional assumption and this means that the observations contain both time series and cross sectional units. As defined by (Brooks 2008), "Panel data will embody information across both time and space". Panel analysis begins with determining the type of regression needed for the study and the panel data models are either fixed effects or random effects models. The panel data methodology has an important advantage which is the assumption that firms are heterogeneous, and this is an advantage over studies that use time series or cross sectional data. Other advantages for panel data are added like being very informative and having more variability and less collinearity.
among the variables, therefore using panel data is better for having unbiased and more reliable results, this is proposed in a book by (Baltagi 2011).

In models with fixed effects, as explained by (Pintea et al 2014), the error component can be correlated with regressors; research hypothesis states no correlation between regressors and random error component. While the random effects model assumes that the error component is a totally random error, and the assumption is that the error does not correlate with regressors (Baum 2001 and Baltagi 2008). The rationale behind random effects model is that, unlike the fixed effects model, the variation across entities is assumed to be random and uncorrelated with the predictor or independent variables included in the model, so the entity’s error term is not correlated with the predictors which allows for time-invariant variables to play a role as explanatory variables (Kohler and Kreuter 2012 and Greene 2008).

**Measurement of the dependent variable**

The majority of recent earnings management literature relies primarily on discretionary accruals as a proxy for earnings management and so this study will use the discretionary accruals as a proxy for earnings management. Most researchers prefer to use the cash flow statement approach as it is more useful than the balance sheet approach (Shah et al., 2009, Soliman and Ragab 2014).

This study will use the cash flow statement approach to calculate the total accruals, so based on that approach the total accruals can be calculated as follows:

\[
TA_t = NI_t - CFO_t
\]

Where: \(TA_t\) : total accruals in year \(t\), \(NI_t\) : net income in year \(t\), \(CFO_t\) : cash flows from operating activities in year \(t\).

Total accruals are not the proxy for earnings management; on the contrary, earnings management is the part of the accruals that managers can have control on and are able to practice manipulations. According to this, the total accruals are divided into two parts which are the discretionary accruals and the non discretionary accruals. So to calculate the discretionary accruals, non discretionary accruals are subtracted from total accruals (Shah and Butt 2009)

\[
TA = DA + NDA
\]

Where: \(TA\) : total accruals, \(DA\) : discretionary accruals, \(NDA\) : non discretionary accruals

Many models and methods exist to calculate the discretionary accruals, the Healy 1985 model, the De Angelo 1986 model, Jones 1991 model and finally the modified cross sectional Jones 1995 model.

Consequently, based on the modified Jones model 1995, that this study uses, the equation to be used in calculating the NDA is as follows: (Uwuigbe et al 2015 and Shah et al 2009)

\[
NDA_t = \beta_1j \frac{[1/At-1]}{A_t} + \beta_2j \frac{[\DeltaREV_t - \DeltaART_t/At-1]}{A_t} + \beta_3j [PPE_t/At-1]
\]

Where: \(NDA_t\) : Non discretionary accruals for firm \(j\) in year \(t\), \(At-1\) : Total assets for firm \(j\) in year \(t-1\), \(\DeltaREV_t\) : Change in the revenues (sales) for firm \(j\) in year \(t\) less revenue in year \(t-1\), \(\DeltaART_t\) : Change in accounts receivables for firm \(j\) in year \(t\) less receivable in year \(t-1\), \(PPE_t\) : Gross properties, plants and equipments for firm \(j\) in year \(t\), \(\beta_1j, \beta_2j, \beta_3j\) are firm specific parameters

In order to find the firm specific parameters to be used in the NDA equation, a regression equation is used to find those parameters and this equation is as follows: (Ahmad et al 2014, Salleh and Haat 2014 and Uwuigbe et al 2015)

\[
TAC_t/At-1 = \beta_1j \frac{[1/At-1]}{A_t} + \beta_2j [(\DeltaREV_t - \DeltaART_t)/A_t-1] + \beta_3j [PPE_t/At-1] + \epsilon_t
\]

After calculating the total accruals using the cash flow statement approach and calculating the non discretionary accruals through the equation of the modified Jones model
1995, the discretionary accruals can then be calculated using the following equation: (Salleh and Haat 2014 and Uwuigbe et al 2015)

\[ DA_{jt} = \frac{TAC_{jt}}{A_{jt}} - 1 - NDA_{jt} \]

**Measurement of the independent variables**

</table>

**Model Specification**

To test for the hypotheses, this research utilizes the following regression model to examine and test for the impact of multiple independent variables which are the firm characteristics on the dependent variable which is the earnings management practice in the 50 most active firms in the Egyptian stock exchange.

\[ DAC = \beta_0 + \beta_1 FSIZE + \beta_2 FLEV + \beta_3 FAGE + \beta_4 AUQUL + \beta_5 FSUR + \varepsilon \]

Where: DAC: is the discretionary accrual, FSIZE: is the firm's size, FLEV: is the firm's financial leverage, FAGE: is the firm's age, AUQUL: is the audit quality, FSUR: is the survival variable and the \( \varepsilon \) is the error term.

**Findings and discussion**

The analysis will start by the descriptive statistics, followed by the correlation analysis and then the results of the regression analysis are shown and discussed to see whether the hypotheses are validated or not. The analysis is done using the Stata program.

**Descriptive Statistics**

The descriptive statistics show the mean, minimum and maximum values and the standard deviation of the dependent and independent variables. The variables used in this research are the independent variables (firm size, firm age, firm financial leverage and firm audit quality) and the dependent variable which is earnings management.

**Table 1: Descriptive statistics**

As it is shown in table 1, the results state that the mean value of the dependent variable (Discretionary Accruals "DAC") for the selected sample of firms is equal to (0.0428084) with a
standard deviation of about (12.9%). This average implies that about (4%) on average of the earnings management practices practiced by the sampled firms, are having an upward direction which means manipulating the earnings level by increasing it.

Moving to the independent variables, the results show that the average firm size for the sample is about 21% with a minimum of 16.9% and a maximum of 24.2% and a standard deviation of 1.59, the second independent variable which is the firms’ financial leverage averaged to 39% of the total assets which means that the average of the firms depend a little bit more on equity rather than debt. The average age for the sampled firms is 27.96 years, while the minimum firm age for the sample is 16 years and the maximum firm age is 41 years. The fourth independent variable is the firms' audit quality which is measured by a dummy variable so the minimum value is 0 and the maximum value is 1 and it has an average of 28% which means that 28% of the sample firms is audited by one of the big four auditing firms.

**Correlation analysis**

This analysis aims to check the relationship between dependent and independent variables as well as the independent variables among each other and helps to check for the multicollinearity problem. It is stated by (Ho 2006) that the correlation must be two tailed if the hypotheses are not stating a particular direction for the relation between the independent variables and the dependent variable and that’s the case in this study.

The Pearson's correlation matrix is used and it shows the degree of correlation between the independent variables and based on (Soliman 2013, cited in Bryman and Cramer 1997), the Pearson's correlation between independent variables should not exceed 0.8 to prove that there is no multicollinearity problem among the variables. As shown in table 2, the highest correlation is between audit quality variable and the firm survival variable with the amount of 0.4128 and this shows that there is no multicollinearity problem between the independent variables used in this research model, as it does not exceed the 0.8.

**Regression Analysis**

Hausman test is carried out for the sample of 60 firms for the period from 2007 to 2011, using the discretionary accruals as a dependent variable. The result indicates an insignificant level equals to (0.1316) compared to (0.05) and this indicated that the random effect regression should be used instead of the fixed effect.

Adjusted R Square = 0.1675  
Model Significance (Prob>chi2) = 0.0000

Table 4: Random Effect GLS Regression

A random effect model is estimated by Generalized Least Squares (GLS) regression as shown in table 4. The model is found to be highly significant as the significance level is shown to be (0.0000) and the adjusted R Square is equal to (0.1675) which means that 16.75% variation in the dependent variable (earnings management) is explained by the independent variables (firm characteristics) this is similar to the results of (Waweru and Riro 2013) conducting a study on Kenyan listed firms. Regarding the significance level between each independent variable and the dependent variable it was found that only the firms’ financial leverage has a significant relationship with earnings management with a significance level of (0.000) leading to the second hypothesis of the study to be accepted, in addition the coefficient is equal to (0.74046090), which shows a positive relationship between both variables, this is similar to the findings of (Weber 2006).

The rest of the independent variables show an insignificant relationship with the dependent variable as their values are greater than 0.05 and even greater than 0.1, as shown in table 4, which leads to the rejection of their hypotheses and these results regarding the relation between the firm size, firm age and firms’ audit quality are similar to the findings of (Al saeed 2006, and Chung et al 2005).

Conclusion

This paper examines the impact of firm characteristics on earnings management in the 50 most active firms listed in the Egyptian stock exchange from the year 2007-2011 taking four firm characteristics to conduct the research model which are the firm size, firm financial leverage, firm age and firm's audit quality. The study extends research on the quality of financial reporting and its importance. The findings are of great importance for future researchers who aim to conduct further studies in this topic in the Egyptian market and generally speaking the findings are important for investors in developing countries as well as other stakeholders as they depend on the reported financial information to take investment and other decisions.

Findings from the tests conducted indicate that only 16.75% change in the firm's earnings management practice is explained by firms' characteristics, which is not a high percentage however very close and similar to other studies analyzing the same relation. Based on the results of this study, the firms’ financial leverage has a significant positive relation with earnings management which gives an indicator for the firms to control the level of leverage as to avoid the existence of the earnings management practice, and this might be a guidance for the stakeholders to focus and understand the leverage level of the firm before taking any decision.

Research limitations and direction for further research
External Validity is defined by (Saunders et al 2009) as the extent to which the research results are generalizable, that is, whether the findings may be equally applicable to other research settings, such as other organizations. Based on the above statement, this research faces several limitations.

First of all, this research showed the effect of only four independent variables constituting the firms’ characteristics. Those are the most commonly used characteristics in the prior literature testing their effect on earnings management. So this could be a limitation as there might be other characteristics that can explain earnings management and raise the level of the adjusted R square. Another limitation is that the research is conducted only on a sample of the 50 most active firms listed in the Egyptian Stock Exchange (EGX). A third limitation is the inability to access all the needed data so this research is constrained only to the firms located in Egypt. Finally, the use of the disclosure book as a data source is considered a limitation as the last disclosure book issued is that of the year ending 2011.

Future research could consider other firm characteristics rather than those used in this study and other independent variables like corporate governance variables and cultural dimensions that might have a greater impact on the dependent variable (earnings management, measured by the discretionary accruals). It is highly recommended for future research to try linking the Egyptian cultural drivers suggested by the social psychologist Geert Hofstede, with the tendency to practice earnings management and to be applied to the Egyptian firms.
